(54) Title: METHODS FOR PROGNOSIS AND TREATMENT OF SOLID TUMORS

(57) Abstract: Solid tumor prognosis genes, and methods, systems and equipment of using these genes for the prognosis and treatment of solid tumors. Prognosis genes for a solid tumor can be identified by the present invention. The expression profiles of these genes in peripheral blood mononuclear cells (PBMCs) are correlated with clinical outcome of the solid tumor. The prognosis genes of the present invention can be used as surrogate markers for predicting clinical outcome of a solid tumor in a patient of interest. These genes can also be used to select a treatment which has a favorable prognosis for the solid tumor of the patient of interest.

WO 2004/097052 A2

METHODS FOR PROGNOSIS AND TREATMENT OF SOLID TUMORS

[0001] The present invention incorporates by reference all materials recorded in the compact discs labeled "Copy 1 – Sequence Listing Part" "Copy 2 – Sequence Listing Part" and "Copy 3 – Sequence Listing Part," each of which includes "Sequence Listing.ST25.txt" (5,454 KB, created April 28, 2004). The present invention also incorporates by reference all materials recorded in the compact discs labeled "Copy 1 – Tables Part," "Copy 2 – Tables Part," and "Copy 3 – Tables Part," each of which includes the following files: "Table 3 - Spearman Correlation of Baseline Expression with Clinical Outcome.txt" (298 KB, created April 28, 2004), "Table 4 - Qualifiers and the Corresponding Entrez and Unigene Accession Nos.txt" (179 KB, created April 28, 2004), "Table 5 - Genes and Gene Titles.txt" (331 KB, created April 28, 2004), and "Table 8 - Cox Regression of Clinical Outcome on Baseline Gene Expression.txt" (294 KB, created April 28, 2004).

CROSS-REFERENCE TO RELATED APPLICATIONS

[0002] The present application claims priority from and incorporates by reference the entire disclosures of U.S. Provisional Patent Application Serial No. 60/466,067, filed April 29, 2003, and U.S. Provisional Patent Application Serial No. 60/538,246, filed January 23, 2004.

TECHNICAL FIELD

[0003] The present invention relates to solid tumor prognosis genes and methods of using these genes for the prognosis or treatment of solid tumors.

BACKGROUND

[0004] Expression profiling studies in primary tissues have demonstrated that there exist transcriptional differences between normal and malignant tissues. See, for example, Su, *et al.*, CANCER RES, 61:7388-7393 (2001); and Ramaswamy, *et al.*, PROC NATL ACAD SCI U.S.A., 98:15149-15151 (2001). Recent clinical analyses have also identified expression profiles within tumors that appear to be highly correlated with certain measures of clinical outcomes. One study has demonstrated that expression profiling of primary tumor biopsies yields prognostic "signatures" that rival or may even out-perform currently

accepted standard measures of risk in cancer patients. See van de Vijver, *et al.*, N ENGL J MED, 347:1999-2009 (2002).

SUMMARY OF THE INVENTION

[0005] The present invention provides methods, systems and equipment for prognosis or selection of treatment of solid tumors. Prognosis genes for a solid tumor can be identified by the present invention. The expression profiles of these genes in peripheral blood mononuclear cells (PBMCs) are correlated with clinical outcome of the solid tumor. These genes can be used as surrogate markers for predicting clinical outcome of the solid tumor in a patient of interest. These genes can also be used to identify or select treatments which have favorable prognoses for the patient of interest.

[0006] In one aspect, the present invention provides methods that are useful for the prognosis or selection of treatment of a solid tumor in a patient of interest. The methods include comparing an expression profile of one or more prognosis genes in a peripheral blood sample of the patient of interest to at least one reference expression profile of the prognosis genes. Each of the prognosis genes is differentially expressed in PBMCs of a first class of patients as compared to PBMCs of a second class of patients. Both classes of patients have a solid tumor, and each class of patients has a different clinical outcome. In many embodiments, the prognosis genes are substantially correlated with a class distinction between the two classes of patients.

[0007] Solid tumors amenable to the present invention include, but are not limited to, renal cell carcinoma (RCC), prostate cancer, head/neck cancer, and other tumors that do not have their origin in blood or lymph cells.

[0008] Clinical outcome can be measured by any clinical indicator. In one embodiment, clinical outcome is determined based on clinical classifications such as complete response, partial response, minor response, stable disease, progressive disease, non-progressive disease, or any combination thereof. In another embodiment, clinical outcome is measured by time to disease progression (TTP) or time to death (TTD). In still another embodiment, clinical outcome is prognosticated by using traditional risk assessment methods, such as Motzer risk classification for RCC. Other patient responses to a therapeutic treatment can also be used to measure clinical outcome. Examples of solid tumor treatments include, but are not limited to, drug therapy (e.g., CCI-779 therapy),

chemotherapy, hormone therapy, radiotherapy, immunotherapy, surgery, gene therapy, anti-angiogenesis therapy, palliative therapy, or any combination thereof.

[0009] In many embodiments, the reference expression profile(s) includes an average expression profile of the prognosis genes in peripheral blood samples of reference patients. In many instances, the reference patients have the same solid tumor as the patient of interest, and the clinical outcome of the reference patients are either known or determinable.

[0010] The peripheral blood samples of the patient of interest and reference patients can be whole blood samples, or blood samples comprising enriched or purified PBMCs. Other types of blood samples can also be employed in the present invention. In one embodiment, all of the peripheral blood samples are baseline samples which are isolated from respective patients prior to a therapeutic treatment of the patients.

[0011] Any comparison method can be used to compare the expression profile of the patient of interest to the reference expression profile(s). In one embodiment, the comparison is based on the absolute or relative peripheral blood expression level of each prognosis gene. In another embodiment, the comparison is based on the ratios between expression levels of two or more prognosis genes. In yet another embodiment, the reference expression profiles include at least two distinct expression profiles, each being derived from a different class of reference patients. The comparison of the expression profile of the patient of interest to the reference expression profiles can be carried out by using methods including, but not limited to, hierarchical clustering, *k*-nearest-neighbors, or weighted-voting algorithm.

[0012] In still another embodiment, the methods of the present invention include selecting a treatment which has a favorable prognosis for the solid tumor in the patient of interest.

[0013] In another aspect, the present invention provides other methods useful for the prognosis or selection of treatment of a solid tumor in a patient of interest. These methods include comparing an expression profile of one or more prognosis genes in a peripheral blood sample of the patient of interest to at least one reference expression profile of the prognosis genes, where each of the prognosis genes is differentially expressed in PBMCs of a first class of patients as compared to PBMCs of a second class of patients. Each of the first and second classes is a subcluster formed by an unsupervised clustering analysis of gene expression profiles in PBMCs of patients who have the solid tumor. In one

embodiment, the majority of the first class of patients has a first clinical outcome, and the majority of the second class of patients has a second clinical outcome.

[0014] In yet another aspect, the present invention further provides methods useful for the prognosis or selection of treatment of a solid tumor in a patient of interest. The methods include comparing an expression profile of one or more prognosis genes in a peripheral blood sample of the patient of interest to at least one reference expression profile of the prognosis genes, where the expression levels of each of the prognosis genes in PBMCs of patients having the solid tumor are correlated with clinical outcomes of these patients. The association between PBMC expression levels and clinical outcome can be determined by a statistical method (e.g., Spearman's rank correlation or Cox proportional hazard regression model) or a class-based correlation metric (e.g., neighborhood analysis). In one embodiment, the solid tumor is RCC, and clinical outcome is measured by patient response to a CCI-779 therapy. In another embodiment, the prognosis genes include at least one gene selected from Tables 6a, 6b, 6c, 6d, 9a, 9b, 9c, 9d, 10, 11, 12, 13, 16, 20, and 21.

[0015] The present invention also features systems useful for the prognosis or selection of treatment of a solid tumor in a patient of interest. The systems include (1) a memory or a storage medium comprising data that represent an expression profile of one or more prognosis genes in a peripheral blood sample of the patient of interest, (2) a storage medium comprising data that represent at least one reference expression profile of the prognosis genes, (3) a program capable of comparing the expression profile of the patient of interest to the reference expression profile, and (4) a processor capable of executing the program. The expression levels of the prognosis genes in PBMCs of patients having the solid tumor are correlated with clinical outcomes of the patients.

[0016] Moreover, the present invention features nucleic acid or protein arrays useful for the prognosis or selection of treatment of a solid tumor in a patient of interest. The nucleic acid or protein arrays include concentrated probes for solid tumor prognosis genes.

[0017] Other features, objects, and advantages of the present invention are apparent in the detailed description that follows. It should be understood, however, that the detailed description, while indicating embodiments of the present invention, is given by way of illustration only, not limitation. Various changes and modifications within the scope of the invention will become apparent to those skilled in the art from the detailed description.

BRIEF DESCRIPTION OF THE DRAWINGS

[0018] The drawings are provided for illustration, not limitation. All drawings in the parallel U.S. patent application, entitled "Methods for Prognosis and Treatment of Solid Tumors" and filed April 29, 2004, are incorporated herein by reference.

[0019] Figure 1A depicts expression profiles of class-correlated genes identified by nearest-neighbor analysis of patients with survival of less than 150 days versus patients with survival of greater than 550 days. The relative expression levels of the class-correlated genes (rows) are indicated for each patient (columns) according to the normalized expression level scale.

[0020] Figure 1B shows the comparison of the signal to noise (S2N) similarity metric scores for class-correlated genes identified in Figure 1A relative to S2N scores for the top 1%, 5%, and 50% of scores for class-correlated genes resulting from randomly permuted data sets.

[0021] Figure 1C illustrates training set cross validation results for predictor gene sets of increasing size. Each predictor set was evaluated by cross validation to identify the predictor set with the highest accuracy for classification of the samples. In these analyses, a 58 gene predictor set (77% accuracy) was the optimal classifier.

[0022] Figure 1D demonstrates cross validation results for each sample using the 58-gene predictor identified in Figure 1C. A leave-one-out cross validation was performed and the prediction strengths were calculated for each sample in the analysis. For the purposes of illustration, confidence scores accompanying calls of "TTD > 550 days" were assigned positive values, while prediction strengths accompanying calls of "TTD < 150 days" were assigned negative values.

[0023] Figure 2A shows the relative gene expression levels of a 42-gene classifier for the comparison of patients with intermediate versus poor Motzer risk classification.

[0024] Figure 2B shows the relative gene expression levels for an 18-gene classifier identified in the comparison of patients with progressive disease versus any other clinical response.

[0025] Figure 2C demonstrates the relative gene expression levels for a 6-gene classifier identified in the comparison of patients in the lower versus upper quartiles of time to disease progression.

[0026] Figure 2D shows the relative gene expression levels for a 52-gene classifier identified in the comparison of patients in the lower versus upper quartiles of survival/time to death.

[0027] Figure 2E depicts the relative expression levels for a 12-gene classifier identified in the comparison of patients with early (time to disease progression < 106 days) versus all other times to disease progression (TTP \geq 106 days).

[0028] Figure 3A illustrates the dendrogram of an unsupervised hierarchical clustering of baseline PBMC profiles in 45 RCC patients using all expressed genes present in at least one sample and possessing a frequency of greater than 10 ppm in at least one sample (5,424 genes total). PBMC expression profiles in the poor prognosis cluster are indicated by subcluster "A," where 9 out of 12 patients with PBMC profiles in this subcluster exhibited survival of less than a year. PBMC expression profiles in the good prognosis cluster are indicated by subcluster "C," where 10 out of 12 patients with PBMC profiles in this subcluster exhibited survival of greater than a year. The median survival for patients in subclusters A, B, C, and D is 281 days, 566 days, 573 days, and 502 days, respectively.

[0029] Figure 3B shows baseline expression profiles of selected genes in RCC patients. The dendrogram of sample relatedness is indicated.

[0030] Figure 4A illustrates the Kaplan-Meier survival curve for patients in the poor and good prognosis subclusters segregated on the basis of gene expression pattern.

[0031] Figure 4B illustrates the Kaplan-Meier survival curve for patients in the poor and good prognosis subclusters segregated on the basis of Motzer risk assessment.

[0032] Figure 5A demonstrates the result of supervised identification of a gene classifier for assigning class membership to patients in the good and poor prognosis subclusters. The relative expression levels of the most class-correlated gene (rows) are indicated for each patient (columns) according to the scale described in Figure 1A.

[0033] Figure 5B shows cross validation results for each sample using the gene classifier of Figure 5A. A leave-one-out cross validation was performed and the confidence scores were calculated for each sample in the analysis. Similar to Figure 1D, for the purposes of illustration, prediction strengths accompanying calls of "survival > 1 year" were assigned positive values, while prediction strengths accompanying calls of "survival < 1 year" were assigned negative values. Asterisks identify the false positives in this clinical assay designed to identify short survival times, and arrowheads indicate false negatives.

[0034] Figure 6A shows the optimal gene classifier for year-long survival identified by nearest-neighbor analysis using a more stringent filter (at least 25% present calls, and an average frequency no less than 5 ppm). A GeneCluster gene selection approach identifies

genes distinguishing patients with survival less than 365 days versus patients with survival greater than 365 days in the training set. The relative expression levels of the most class-correlated genes (rows) are indicated for each of the patients in the training set (columns) according to the scale described in Figure 1A.

[0035] Figure 6B evaluates prediction accuracy of gene classifiers of increasing size. Accuracy of class assignment for gene classifiers containing between 2 and 60 genes in steps of 2, and 60-200 genes in steps of 10, were evaluated by leave-one-out cross validation on the training set of samples. The smallest predictive model with the highest accuracy was selected (20 gene predictor, indicated by the arrow).

[0036] Figure 6C demonstrates the result of evaluation of the optimal predictive model of Figure 6B on an untested set of RCC PBMC profiles. A *k*-nearest-neighbors algorithm using the 20 gene classifier was used to assign class membership to the remaining 14 PBMC profiles, and the prediction strengths associated with the class assignments are presented for each sample in the analysis. For the purposes of illustration, confidence scores accompanying calls of "TTD < 365 days" were assigned positive values, while confidence scores accompanying calls of "TTD > 365 days" were assigned negative values. The overall accuracy of the gene classifier was 72%. By defining the clinical assay as the identification of favorable outcome, eight of eight patients with favorable outcome were correctly identified as having survival greater than one year (positive predictive value of 100%).

[0037] Figure 7A illustrates the optimal gene classifier for greater than 106 day time to progression identified by nearest-neighbor analysis using a more stringent filter (at least 25% present calls, and an average frequency no less than 5 ppm). A GeneCluster gene selection approach identifies genes distinguishing patients with TTP less than 106 days versus patients with TTP greater than 106 days in the training set. The relative expression levels of the most class-correlated genes (rows) are indicated for each of the patients in the training set (columns) according to the scale of Figure 1A.

[0038] Figure 7B indicates prediction accuracy of gene classifiers of increasing size. Accuracy of class assignment for gene classifiers containing between 2 and 60 genes in steps of 2, and 60-200 genes in steps of 10, were evaluated by leave-one-out cross validation on the training set of samples. The smallest predictive model with the highest accuracy was selected (30 gene predictor, indicated by the arrow).

[0039] Figure 7C shows the result of evaluation of the optimal predictive model of Figure 7B on an untested set of RCC PBMC profiles. A *k*-nearest-neighbors algorithm using the 30 gene classifier was used to assign class membership to the remaining 14 PBMC profiles, and the prediction strengths associated with the class assignments are presented for each sample in the analysis. For the purposes of illustration, confidence scores accompanying calls of "TTP < 106 days" were assigned positive values, while confidence scores accompanying calls of "TTD > 106 days" were assigned negative values. The overall accuracy of the gene classifier was 85%. By defining the clinical assay as the identification of favorable outcome, eight of ten patients with favorable outcome were correctly identified as having TTP greater than one 106 days (positive predictive value of 80%) and three of three patients with poor outcome were correctly predicted to have TTP less than 106 days (negative predictive value 100%).

DETAILED DESCRIPTION

[0040] The present invention provides methods that are useful for prognosis or selection of treatment of solid tumors. These methods employ prognosis genes that are differentially expressed in peripheral blood samples of solid tumor patients who have different clinical outcomes. In many embodiments, the peripheral blood expression profiles of these prognosis genes are correlated with patients' clinical outcome or prognosis under a statistical method or a correlation model. In many other embodiments, solid tumor patients can be divided into at least two classes based on patients' clinical outcome or prognosis, and the prognosis genes are substantially correlated with a class distinction between these two classes of patients under a neighborhood analysis.

[0041] The prognosis genes of the present invention can be used as surrogate markers for the prediction of clinical outcome of solid tumors. The prognosis genes of the present invention can also be used for the identification of optimal treatments of solid tumors. Different patients may have distinct clinical responses to a therapeutic treatment due to individual heterogeneity of the molecular mechanism of the disease. The identification of gene expression patterns that correlate with patient response allows clinicians to select treatments based on predicted patient responses and thereby avoid adverse reactions. This provides improved power and safety of clinical trials and increased benefit/risk ratio for drugs and other therapeutic treatments. Peripheral blood is a tissue that can be routinely obtained from patients in a minimally invasive manner. By determining the correlation

between patient outcome and gene expression profiles in peripheral blood samples, the present invention represents a significant advance in clinical pharmacogenomics and solid tumor treatment.

[0042] Various aspects of the invention are described in further detail in the following subsections. The use of subsections is not meant to limit the invention. Each subsection may apply to any aspect of the invention. In this application, the use of "or" means "and/or" unless stated otherwise.

I. General Methods for Identifying Solid Tumor Prognosis Genes

[0043] Previous studies demonstrated that baseline expression profiles in PBMCs from solid tumor patients were significantly distinct from those of disease-free subjects. See U.S. Provisional Application Serial No. 60/459,782, filed April 3, 2003, U.S. Provisional Application Serial No. 60/427,982, filed November 21, 2002, and U.S. Patent Application Serial No. 10/717,597, filed November 21, 2003, all of which are incorporated herein by reference. Studies also showed that gene expression profiles in PBMCs were predictive of anti-cancer drug activity *in vivo*. See U.S. Provisional Application Serial No. 60/446,133, filed February 11, 2003, and U.S. Patent Application Serial No. 10/775,169, filed February 11, 2004, both of which are incorporated herein by reference. In addition, studies indicated that PBMC baseline expression profiles were correlated with clinical outcomes of RCC or other non-blood diseases. See U.S. Provisional Application Serial No. 60/466,067, filed April 29, 2003, which is incorporated herein by reference.

[0044] The present invention further evaluates the correlation between peripheral blood gene expression and clinical outcome of solid tumors. Prognosis genes for a variety of solid tumors can be identified by the present invention. These genes are differentially expressed in peripheral blood samples of solid tumor patients who have different clinical outcomes. In many embodiments, the peripheral blood expression profiles of the prognosis genes of the present invention are correlated with patient outcome under statistical methods or correlation models. Exemplary statistical methods and correlation models include, but are not limited to, Spearman's rank correlation, Cox proportional hazard regression model, ANOVA/t test, nearest-neighbor analysis, and other rank tests, survival models or class-based correlation metrics.

[0045] Solid tumors amenable to the present invention include, without limitation, RCC, prostate cancer, head/neck cancer, ovarian cancer, testicular cancer, brain tumor, breast cancer, lung cancer, colon cancer, pancreas cancer, stomach cancer, bladder cancer, skin cancer, cervical cancer, uterine cancer, and liver cancer. In one embodiment, the solid tumors do not have their origin in blood or lymph (hematopoietic) cells. Solid tumors can be measured or evaluated using direct or indirect visualization procedures. Suitable visualization methods include, but are not limited to, scans (such as X-rays, computerized axial tomography (CT), magnetic resonance imaging (MRI), positron emission tomography (PET), or ultrasonography (U/S)), biopsy, palpation, endoscopy, laparoscopy, and other suitable means as appreciated by those skilled in the art.

[0046] Clinical outcome of solid tumors can be assessed by numerous criteria. In many embodiments, clinical outcome is assessed based on patients' response to a therapeutic treatment. Examples of clinical outcome measures include, without limitation, complete response, partial response, minor response, stable disease, progressive disease, time to disease progression (TTP), time to death (TTD or Survival), or any combination thereof. Examples of solid tumor treatments include, without limitation, drug therapy (e.g., CCI-779 therapy), chemotherapy, hormone therapy, radiotherapy, immunotherapy, surgery, gene therapy, anti-angiogenesis therapy, palliative therapy, or any combination thereof, or other conventional or non-conventional therapies.

[0047] In one embodiment, clinical outcome is evaluated based on the WHO Reporting Criteria, such as those described in WHO Publication, No. 48 (World Health Organization, Geneva, Switzerland, 1979). Under the Criteria, uni- or bidimensionally measurable lesions are measured at each assessment. When multiple lesions are present in any organ, up to 6 representative lesions can be selected, if available.

[0048] In another embodiment, clinical outcome is determined based on a classification system composed of clinical categories such as complete response, partial response, minor response, stable disease, progressive disease, or any combination thereof. "Complete response" (CR) means complete disappearance of all measurable and evaluable disease, determined by two observations not less than 4 weeks apart. There is no new lesion and no disease related symptom. "Partial response" (PR) in reference to bidimensionally measurable disease means decrease by at least about 50% of the sum of the products of the largest perpendicular diameters of all measurable lesions as determined by 2 observations not less than 4 weeks apart. "Partial response" in reference to unidimensionally measurable

disease means decrease by at least about 50% in the sum of the largest diameters of all lesions as determined by 2 observations not less than 4 weeks apart. It is not necessary for all lesions to have regressed to qualify for partial response, but no lesion should have progressed and no new lesion should appear. The assessment should be objective. "Minor response" in reference to bidimensionally measurable disease means about 25% or greater decrease but less than about 50% decrease in the sum of the products of the largest perpendicular diameters of all measurable lesions. "Minor response" in reference to unidimensionally measurable disease means decrease by at least about 25% but less than about 50% in the sum of the largest diameters of all lesions.

[0049] "Stable disease" (SD) in reference to bidimensionally measurable disease means less than about 25% decrease or less than about 25% increase in the sum of the products of the largest perpendicular diameters of all measurable lesions. "Stable disease" in reference to unidimensionally measurable disease means less than about 25% decrease or less than about 25% increase in the sum of the diameters of all lesions. No new lesions should appear. "Progressive disease" (PD) refers to a greater than or equal to about a 25% increase in the size of at least one bidimensionally (product of the largest perpendicular diameters) or unidimensionally measurable lesion or appearance of a new lesion. The occurrence of pleural effusion or ascites is also considered as progressive disease if this is substantiated by positive cytology. Pathological fracture or collapse of bone is not necessarily evidence of disease progression.

[0050] In yet another embodiment, overall subject tumor response for uni- and bidimensionally measurable disease is determined according to Table 1.

Table 1. Overall Subject Tumor Response

| Response in Bidimensionally Measurable Disease | Response in Unidimensionally Measurable Disease | Overall Subject Tumor Response |
|--|---|-----------------------------------|
| PD | Any | PD |
| Any | PD | PD |
| SD | SD or PR | SD |
| SD | CR | PR |
| PR | SD or PR or CR | PR |
| CR | SD or PR | PR |
| CR | CR | CR |

[0051] Overall subject tumor response for non-measurable disease can be assessed, for instance, in the following situations:

a) Overall complete response: if non-measurable disease is present, it should disappear completely. Otherwise, the subject cannot be considered as an "overall complete responder."

b) Overall progression: in case of a significant increase in the size of non-measurable disease or the appearance of a new lesion, the overall response will be progression.

[0052] Clinical outcome can also be assessed by other criteria. For instance, clinical outcome can be measured by TTP or TTD. TTP refers to the interval from the date of initiation of a therapeutic treatment until the first day of measurement of progressive disease. TTD refers to the interval from the date of initiation of a therapeutic treatment to the time of death, or censored at the last date known alive.

[0053] Moreover, clinical outcome can include prognoses based on traditional clinical risk assessment methods. In many cases, these risk assessment methods employ numerous prognostic factors to classify patients into different prognosis or risk groups. One example is Motzer risk assessment for RCC, as described in Motzer, *et al.*, J CLIN ONCOL, 17:2530-2540 (1999). Patients in different risk groups may have different responses to a therapy.

[0054] Peripheral blood samples employed in the present invention can be isolated from solid tumor patients at any disease or treatment stage. In one embodiment, the peripheral blood samples are isolated from solid tumor patients prior to a therapeutic treatment. These blood samples are "baseline samples" with respect to the therapeutic treatment.

[0055] A variety of peripheral blood samples can be used in the present invention. In one embodiment, the peripheral blood samples are whole blood samples. In another embodiment, the peripheral blood samples comprise enriched PBMCs. By "enriched," it means that the percentage of PBMCs in the sample is higher than that in whole blood. In some cases, the PBMC percentage in an enriched sample is at least 1, 2, 3, 4, 5 or more times higher than that in whole blood. In some other cases, the PBMC percentage in an enriched sample is at least 90%, 95%, 98%, 99%, 99.5%, or more. Blood samples containing enriched PBMCs can be prepared using any method known in the art, such as Ficoll gradients centrifugation or CPTs (cell purification tubes).

[0056] The relationship between peripheral blood gene expression profiles and patient outcome can be evaluated using global gene expression analyses. Methods suitable for this purpose include, but are not limited to, nucleic acid arrays (such as cDNA or oligonucleotide arrays), 2-dimensional SDS-polyacrylamide gel electrophoresis/mass spectrometry, and other high throughput nucleotide or polypeptide detection techniques.

[0057] Nucleic acid arrays allow for quantitative detection of the expression levels of a large number of genes at one time. Examples of nucleic acid arrays include, but are not limited to, Genechip[®] microarrays from Affymetrix (Santa Clara, CA), cDNA microarrays from Agilent Technologies (Palo Alto, CA), and bead arrays described in U.S. Patent Nos. 6,288,220 and 6,391,562.

[0058] The polynucleotides to be hybridized to nucleic acid arrays can be labeled with one or more labeling moieties to allow for detection of hybridized polynucleotide complexes. The labeling moieties can include compositions that are detectable by spectroscopic, photochemical, biochemical, bioelectronic, immunochemical, electrical, optical or chemical means. Exemplary labeling moieties include radioisotopes, chemiluminescent compounds, labeled binding proteins, heavy metal atoms, spectroscopic markers such as fluorescent markers and dyes, magnetic labels, linked enzymes, mass spectrometry tags, spin labels, electron transfer donors and acceptors, and the like. Unlabeled polynucleotides can also be employed. The polynucleotides can be DNA, RNA, or a modified form thereof.

[0059] Hybridization reactions can be performed in absolute or differential hybridization formats. In the absolute hybridization format, polynucleotides derived from one sample, such as PBMCs from a patient in a selected outcome class, are hybridized to the probes on a nucleic acid array. Signals detected after the formation of hybridization complexes correlate to the polynucleotide levels in the sample. In the differential hybridization format, polynucleotides derived from two biological samples, such as one from a patient in a first outcome class and the other from a patient in a second outcome class, are labeled with different labeling moieties. A mixture of these differently labeled polynucleotides is added to a nucleic acid array. The nucleic acid array is then examined under conditions in which the emissions from the two different labels are individually detectable. In one embodiment, the fluorophores Cy3 and Cy5 (Amersham Pharmacia Biotech, Piscataway N.J.) are used as the labeling moieties for the differential hybridization format.

[0060] Signals gathered from nucleic acid arrays can be analyzed using commercially available software, such as those provided by Affymetrix or Agilent Technologies. Controls, such as for scan sensitivity, probe labeling and cDNA/cRNA quantitation, can be included in the hybridization experiments. In many embodiments, the nucleic acid array expression signals are scaled or normalized before being subject to further analysis. For instance, the expression signals for each gene can be normalized to take into account variations in hybridization intensities when more than one array is used under similar test conditions. Signals for individual polynucleotide complex hybridization can also be normalized using the intensities derived from internal normalization controls contained on each array. In addition, genes with relatively consistent expression levels across the samples can be used to normalize the expression levels of other genes. In one embodiment, the expression levels of the genes are normalized across the samples such that the mean is zero and the standard deviation is one. In another embodiment, the expression data detected by nucleic acid arrays are subject to a variation filter which excludes genes showing minimal or insignificant variation across all samples.

[0061] The gene expression data collected from nucleic acid arrays can be correlated with clinical outcome using a variety of methods. Suitable correlation methods include, but are not limited to, statistical methods (such as Spearman's rank correlation, Cox proportional hazard regression model, ANOVA/t test, or other suitable rank tests or survival models) and class-based correlation metrics (such as nearest-neighbor analysis).

[0062] In one aspect, class-based correlation metrics are used to identify the correlation between peripheral blood gene expression and clinical outcome. In one embodiment, patients with a specified solid tumor are divided into at least two classes based on their clinical stratifications. The correlation between peripheral blood gene expression (e.g., in PBMCs) and clinical outcome is analyzed by a supervised cluster algorithm. Exemplary supervised clustering algorithms include, but are not limited to, nearest-neighbor analysis, support vector machines, and SPLASH. Under the supervised cluster algorithms, clinical outcome of each class of patients is either known or determinable. Genes that are differentially expressed in peripheral blood cells (e.g., PBMCs) of one class of patients relative to the other class of patients can be identified. In many cases, the genes thus identified are substantially correlated with a class distinction between the two classes of patients. The genes thus identified can be used as surrogate markers for predicting clinical outcome of the solid tumor in a patient of interest.

[0063] In another embodiment, patients with a specified solid tumor can be divided into at least two classes based on gene expression profiles in their peripheral blood cells. Methods suitable for this purpose include unsupervised clustering algorithms, such as self-organized maps (SOMs), k-means, principal component analysis, and hierarchical clustering. A substantial number (e.g., at least 50%, 60%, 70%, 80%, 90%, or more) of patients in one class may have a first clinical outcome, and a substantial number of patients in the other class may have a second clinical outcome. Genes that are differentially expressed in the peripheral blood cells of one class of patients relative to the other class of patients can be identified. These genes are prognosis genes for the solid tumor.

[0064] In yet another embodiment, patients with a specified solid tumor can be divided into three or more classes based on their clinical stratifications or peripheral blood gene expression profiles. Multi-class correlation metrics can be employed to identify genes that are differentially expressed in these classes. Exemplary multi-class correlation metrics include, but are not limited to, GeneCluster 2 software provided by MIT Center for Genome Research at Whitehead Institute (Cambridge, MA).

[0065] In a further embodiment, nearest-neighbor analysis (also known as neighborhood analysis) is used to analyze gene expression data gathered from nucleic acid arrays. The algorithm for neighborhood analysis is described in Golub, *et al.*, SCIENCE, 286: 531-537 (1999), Slonim, *et al.*, PROCS. OF THE FOURTH ANNUAL INTERNATIONAL CONFERENCE ON COMPUTATIONAL MOLECULAR BIOLOGY, Tokyo, Japan, April 8 - 11, p263-272 (2000), and U.S. Patent No. 6,647,341, all of which are incorporated herein by reference. Under one form of the neighborhood analysis, the expression profile of each gene can be represented by an expression vector $g = (e_1, e_2, e_3, \dots, e_n)$, where e_i corresponds to the expression level of gene "g" in the i th sample. A class distinction can be represented by an idealized expression pattern $c = (c_1, c_2, c_3, \dots, c_n)$, where $c_i = 1$ or -1 , depending on whether the i th sample is isolated from class 0 or class 1. Class 0 may include patients having a first clinical outcome, and class 1 includes patients having a second clinical outcome. Other forms of class distinction can also be employed. Typically, a class distinction represents an idealized expression pattern, where the expression level of a gene is uniformly high for samples in one class and uniformly low for samples in the other class.

[0066] The correlation between gene "g" and the class distinction can be measured by a signal-to-noise score:

$$P(g,c) = [\mu_1(g) - \mu_2(g)] / [\sigma_1(g) + \sigma_2(g)]$$

where $\mu_1(g)$ and $\mu_2(g)$ represent the means of the log-transformed expression levels of gene "g" in class 0 and class 1, respectively, and $\sigma_1(g)$ and $\sigma_2(g)$ represent the standard deviation of the log-transformed expression levels of gene "g" in class 0 and class 1, respectively. A higher absolute value of a signal-to-noise score indicates that the gene is more highly expressed in one class than in the other. In one embodiment, the samples used to derive the signal-to-noise score comprise enriched or purified PBMCs. Thus, the signal-to-noise score $P(g,c)$ can represent a correlation between the class distinction and the expression level of gene "g" in PBMCs.

[0067] The correlation between gene "g" and the class distinction can also be measured by other methods, such as by the Pearson correlation coefficient or the Euclidean distance, as appreciated by those skilled in the art.

[0068] The significance of the correlation between peripheral blood gene expression patterns and the class distinction can be evaluated using a random permutation test. An unusually high density of genes within the neighborhoods of the class distinction, as compared to random patterns, suggests that many genes have expression patterns that are significantly correlated with the class distinction. The correlation between genes and the class distinction can be diagrammatically viewed through a neighborhood analysis plot, in which the y-axis represents the number of genes within various neighborhoods around the class distinction and the x-axis indicates the size of the neighborhood (i.e., $P(g,c)$). Curves showing different significance levels for the number of genes within corresponding neighborhoods of randomly permuted class distinctions can also be included in the plot.

[0069] In one embodiment, the prognosis genes of the present invention are substantially correlated with a class distinction between two outcome classes. In one example, the prognosis genes are above the median significance level in the neighborhood analysis plot. This means that the correlation measure $P(g,c)$ for each prognosis gene is such that the number of genes within the neighborhood of the class distinction having the size of $P(g,c)$ is greater than the number of genes within the corresponding neighborhoods of randomly permuted class distinctions at the median significance level. In another example, the employed prognosis genes are above the 10%, 5%, 2%, or 1% significance level. As used herein, x% significance level means that x% of random neighborhoods contain as many genes as the real neighborhood around the class distinction.

[0070] Class predictors can be constructed using the prognosis genes of the present invention. These class predictors are useful for assigning class membership to solid tumor

patients. In one embodiment, the prognosis genes in a class predictor are limited to those shown to be significantly correlated with the class distinction by the permutation test, such as those at above the 1%, 2%, 5%, 10%, 20%, 30%, 40%, or 50% significance level. In another embodiment, the expression level of each prognosis gene in a class predictor is substantially higher or substantially lower in PBMCs of one class of patients than in the other class of patients. In still another embodiment, the prognosis genes in a class predictor have top absolute values of $P(g,c)$. In yet another embodiment, the p-value under a Student's *t*-test (e.g., two-tailed distribution, two sample unequal variance) for each differentially expressed prognosis gene is no more than 0.05, 0.01, 0.005, 0.001, 0.0005, 0.0001, or less.

[0071] In a further embodiment, the class predictors of the present invention have at least 50% accuracy for leave-one-out cross validation. In another embodiment, the class predictors of the present invention have at least 60%, 70%, 80%, 90%, 95%, or 99% accuracy for leave-one-out cross validation.

[0072] In another aspect, the correlation between peripheral blood gene expression profiles and clinical outcome can be evaluated by statistical methods. Clinical outcome suitable for these analyses includes, but are not limited to, TTP, TTD, and other time-associated clinical indicators. One exemplary statistical method employs Spearman's rank correlation coefficient, which has the formula of:

$$r_s = SS_{UV} / (SS_{UU} SS_{VV})^{1/2}$$

where $SS_{UV} = \sum U_i V_i - [(\sum U_i)(\sum V_i)]/n$, $SS_{UU} = \sum V_i^2 - [(\sum V_i)^2]/n$, and $SS_{VV} = \sum U_i^2 - [(\sum U_i)^2]/n$. U_i is the expression level ranking of a gene of interest, V_i is the ranking of the clinical outcome, and n represents the number of patients. The shortcut formula for Spearman's rank correlation coefficient is $r_s = 1 - (6 \times \sum d_i^2) / [n(n^2 - 1)]$, where $d_i = U_i - V_i$. The Spearman's rank correlation is similar to the Pearson's correlation except that it is based on ranks and is thus more suitable for data that is not normally distributed. See, for example, Snedecor and Cochran, *STATISTICAL METHODS*, Eight edition, Iowa State University Press, Ames, Iowa, 503 pp, 1989. The correlation coefficient is tested to assess whether it differs significantly from a value of 0 (i.e., no correlation).

[0073] The correlation coefficients for each prognosis gene identified by the Spearman's rank correlation can be either positive or negative, provided that the correlation is statistically significant. In many embodiments, the p-value for each prognosis gene thus identified is no more than 0.05, 0.01, 0.005, 0.001, 0.0005, 0.0001, or less. In many other

embodiments, the Spearman correlation coefficients of the prognosis genes thus identified have absolute values of at least 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, or more.

[0074] Another exemplary statistical method is Cox proportional hazard regression model, which has the formula of:

$$\log h_i(t) = \alpha(t) + \beta_j x_{ij}$$

where $h_i(t)$ is the hazard function that assesses the instantaneous risk of demise at time t , conditional on survival to that time, $\alpha(t)$ is the baseline hazard function, and x_{ij} is a covariate which may represent, for example, the expression level of prognosis gene j in a peripheral blood sample. See Cox, JOURNAL OF THE ROYAL STATISTICAL SOCIETY, SERIES B 34:187 (1972). Additional covariates, such as interactions between covariates, can also be included in Cox proportional hazard model. As used herein, the terms "demise" or "survival" are not limited to real death or survival. Instead, these terms should be interpreted broadly to cover any type of time-associated events, such as TTP. In many cases, the p-values for the correlation under Cox proportional hazard regression model are no more than 0.05, 0.01, 0.005, 0.001, 0.0005, 0.0001, or less. The p-values for the prognosis genes identified under Cox proportional hazard regression model can be determined by the likelihood ratio test, Wald test, the Score test, or the log-rank test. In one embodiment, the hazard ratios for the prognosis genes thus identified are at least 1.5, 2, 3, 4, 5, or more. In another embodiment, the hazard ratios for the prognosis genes thus identified are no more than 0.67, 0.5., 0.33, 0.25., 0.2, or less.

[0075] Other rank tests, scores, measurements, or models can also be employed to identify prognosis genes whose expression profiles in peripheral blood samples are correlated with clinical outcome of solid tumors. These tests, scores, measurements, or models can be either parametric or nonparametric, and the regression may be either linear or non-linear. Many statistical methods and correlation/regression models can be carried out using commercially available programs.

[0076] Other methods capable of identifying genes differentially expressed in peripheral blood cells of one class of patients relative to another class of patients can be used. These methods include, but are not limited, RT-PCR, Northern Blot, *in situ* hybridization, and immunoassays such as ELISA, RIA or Western Blot. The expression levels of genes thus identified can be substantially higher or substantially lower in peripheral blood cells (e.g., PBMCs) of one class of patients than in another class of patients. In some cases, the average peripheral blood expression level of a prognosis gene

in PBMCs of one class of patients can be at least 2, 3, 4, 5, 10, 20, or more folds higher or lower than that in another class of patients. In many embodiments, the p-value of an appropriate statistical significance test (e.g., Student's t-test) for the difference between average expression levels is no more than 0.05, 0.01, 0.005, 0.001, 0.0005, 0.0001, or less.

[0077] Prognosis genes for other non-blood diseases can be similarly identified according to the present invention, provided that the correlation between peripheral blood gene expression and clinical outcome of these diseases is statistically significant. The peripheral blood expression patterns of the prognosis genes thus identified are indicative of clinical outcome of these diseases.

II. Identification of RCC Prognosis Genes

[0078] RCC comprises the majority of all cases of kidney cancer and is one of the ten most common cancers in industrialized countries, comprising 2% of adult malignancies and 2% of cancer-related deaths. Several prognostic factors and scoring indices have been developed for patients diagnosed with RCC, typified by multivariate assessments of several key indicators. As an example, one prognostic scoring system employs the five prognostic factors proposed by Motzer, *et al.*, *supra*— namely, Karnofsky performance status, serum lactate dehydrogenase, hemoglobin, serum calcium, and presence/absence of prior nephrectomy.

[0079] The present invention identifies numerous RCC prognosis genes whose peripheral blood expression profiles correlate with patient outcome in CCI-779 therapy. In a clinical trial, the cytostatic mTOR inhibitor CCI-779 was evaluated in RCC patients for its anti-cancer effect. PBMCs collected prior to CCI-779 therapy were analyzed on oligonucleotide arrays in order to determine whether mononuclear cells from RCC patients possessed transcriptional patterns predictive of patient outcome. The results of both supervised and unsupervised analyses indicated that transcriptional profiles in the surrogate tissue of PBMCs from RCC patients prior to treatment with CCI-779 are significantly correlated with patient outcome.

[0080] PBMCs were isolated prior to CCI-779 therapy from peripheral blood of 45 advanced RCC patients (18 females and 27 males) participating in a phase 2 clinical trial study. Written informed consent for the pharmacogenomic portion of the clinical study was received for all individuals and the project was approved by the local Institutional Review

Boards at the participating clinical sites. RCC tumors of patients were classified at the clinical sites as conventional (clear cell) carcinomas (24), granular (1), papillary (3), or mixed subtypes (7). Ten tumors were classified as unknown. RCC patients were primarily of Caucasian descent (44 Caucasian, 1 African-American) and had a mean age of 58 years (range of 40 - 78 years). Inclusion criteria included patients with histologically confirmed advanced renal cancer who had received prior therapy for advanced disease, or who had not received prior therapy for advanced disease but were not appropriate candidates to receive high doses of IL-2 therapy. Other inclusion criteria included patients with (1) bi-dimensionally measurable evidence of disease; (2) evidence of progression of the disease prior to study entry; (3) an age of 18 years or older; (4) ANC > 1500/ μ L, platelet > 100,000/ μ L and hemoglobin > 8.5 g/dL; (5) adequate renal function evidenced by serum creatinine < 1.5 x upper limit of normal; (6) adequate hepatic function evidenced by bilirubin < 1.5 x upper limit of normal and AST < 3x upper limit of normal (or AST < 5x upper limit of normal if liver metastases were present); (7) serum cholesterol < 350 mg/dL, triglycerides < 300 mg/dL; (8) ECOG performance status 0-1; and (9) a life expectancy of at least 12 weeks. Exclusion criteria included patients who had (1) the presence of known CNS metastases; (2) surgery or radiotherapy within 3 weeks of start of dosing; (3) chemotherapy or biologic therapy for RCC within 4 weeks of start of dosing; (4) treatment with a prior investigational agent within 4 weeks of start of dosing; (5) immunocompromised status including those known to be HIV positive, or receiving concurrent use of immunosuppressive agents including corticosteroids; (6) active infections; (7) required treatment with anticonvulsant therapy; (8) presence of unstable angina/myocardial infarction within 6 months/ongoing treatment of life-threatening arrhythmia; (9) history of prior malignancy in past 3 years; (10) hypersensitivity to macrolide antibiotics; and (11) pregnancy or any other illness which would substantially increase the risk associated with participation in the study.

[0081] These advanced RCC patients were treated with one of 3 doses of CCI-779 (25 mg, 75 mg, or 250 mg) administered as a 30 minute intravenous (IV) infusion once weekly for the duration of the trial. CCI-779 is an ester analog of the immunosuppressant rapamycin and as such is a potent, selective inhibitor of the mammalian target of rapamycin. The mammalian target of rapamycin (mTOR) activates multiple signaling pathways, including phosphorylation of p70s6kinase, which results in increased translation of 5' TOP mRNAs encoding proteins involved in translation and entry into the G1 phase of the cell

cycle. By virtue of its inhibitory effects on mTOR and cell cycle control, CCI-779 functions as a cytostatic and immunosuppressive agent.

[0082] Clinical staging and size of residual, recurrent or metastatic disease were recorded prior to treatment and every 8 weeks following initiation of CCI-779 therapy. Tumor size was measured in centimeters and reported as the product of the longest diameter and its perpendicular. Measurable disease was defined as any bidimensionally measurable lesion where both diameters > 1.0 cm by CT-scan, X-ray or palpation. Tumor response was determined by the sum of the products of all measurable lesions. The categories for assignment of clinical response were given by the clinical protocol definitions (i.e., progressive disease, stable disease, minor response, partial response, and complete response). The category for assignment of prognosis under the Motzer risk assessment (favorable vs intermediate vs poor) was also used. Among the 45 RCC patients, 6 were assigned a favorable risk assessment, 17 patients possessed an intermediate risk score, and 22 patients received a poor prognosis classification. In addition to the categorical classifications, overall survival and time to disease progression were also monitored as clinical endpoints.

[0083] HgU95A genechips (manufactured by Affymetrix) were used to detect baseline expression profiles in PBMCs of the RCC patients prior to the CCI-779 therapy. Each HgU95A genechip comprises over 12,600 human sequences according to the Affymetrix Expression Analysis Technical Manual. RNA transcripts were first isolated from PBMCs of the RCC patients. cRNA was then prepared and hybridized to the genechips according to protocols described in the Affymetrix's Expression Analysis Technical Manual. Hybridization signals were collected, scaled, and normalized before being subject to further analysis. In one example, the log of the expression level for each gene was normalized across the samples such that the mean is zero and the standard deviation is one.

[0084] The expression profiling analysis revealed that of the 12,626 genes on the HgU95A chip, 5,424 genes met the initial criteria (i.e., at least 1 present call across the data set and at least 1 frequency ≥ 10 ppm). On average, 4,023 transcripts were detected as "present" in any given RCC PBMC profile.

[0085] In an initial assessment of the expression data in baseline PBMCs, pairwise correlations were calculated to assess the association between gene expression levels measured by HgU95A Affymetrix microarrays and continuous measures of clinical

outcome. Correlations were run using expression levels from each of 5,424 qualifiers that passed the initial criteria. Correlations were run for two clinical measures (TTD and TTP) and for one measure of baseline expression level (\log_2 -transformed scaled frequency in units of ppm).

[0086] In one example, Spearman's rank correlations were computed. The p-value for the hypothesis that the correlation was equal to 0 was calculated for each pairwise correlation. For each comparison between clinical outcome and gene expression, the number of tests that were nominally significant out of the 5,424 tests performed was calculated for five Type I (i.e. false-positive) error levels. To adjust for the fact that 5,424 non-independent tests were performed, a permutation-based approach was employed to evaluate how often the observed number of significance tests would be found under the null hypothesis of no correlation.

[0087] The overall results for Spearman's rank correlation comparisons of clinical outcome with baseline expression levels (\log_2 -transformed scaled frequency) are summarized in Tables 2a and 2b. Each table shows alpha confidence levels (" α "), the observed numbers of transcripts that have nominally significant Spearman correlations with the clinical outcome of interest ("Observed Number"), and the percentage of permutations for which number of nominally significant Spearman correlations equals or exceeds the number observed ("%-age of Permutations"). Evidence for association between clinical outcome and baseline gene expression in PBMCs was significant for both TTD and TTP.

Table 2a. Spearman Correlations of Clinical Outcome with Baseline Expression Levels in PBMCs of RCC Patients in CCI-779 Therapy (n = 45 patients)

| Time to Disease Progression | | |
|-----------------------------|---|---|
| α | Observed Number of Nominally Significant Spearman Correlations* | %-age of Permutations for which Number of Nominally Significant Spearman Correlations equals or exceeds observed number |
| 0.1 | 1127 | 5.3% (53/1000) |
| 0.05 | 749 | 3.8% (38/1000) |
| 0.01 | 248 | 3.1% (31/1000) |
| 0.005 | 159 | 2.6% (26/1000) |
| 0.001 | 51 | 2.5% (25/1000) |

* based on 5,424 genes (filtered by at least one Present and at least one frequency ≥ 10 ppm)

Table 2b. Spearman Correlations of Clinical Outcome with Baseline Expression Levels in PBMCs of RCC Patients in CCI-779 Therapy (n = 45 patients)

| Time to Death | | |
|---------------|---|---|
| α | Observed Number of Nominally Significant Spearman Correlations* | %-age of Permutations for which Number of Nominally Significant Spearman Correlations equals or exceeds observed number |
| 0.1 | 1604 | 0.1% (1/1000) |
| 0.05 | 1117 | 0.1% (1/1000) |
| 0.01 | 436 | 0.1% (1/1000) |
| 0.005 | 289 | 0.1% (1/1000) |
| 0.001 | 105 | 0.3% (3/1000) |

* based on 5,424 genes (filtered by at least one Present and at least one frequency ≥ 10 ppm)

[0088] Table 3 lists the results of the Spearman's rank correlation analyses for all of the 5,424 genes that met the initial criteria. Each gene has a corresponding qualifier on the HgU95A genechip, and each qualifier represents multiple oligonucleotide probes that are stably attached to discrete regions on the HgU95A genechip. According to the design, RNA transcripts of a gene, or the complements thereof, are expected to hybridize under nucleic acid array hybridization conditions to the corresponding qualifier on the HgU95A genechip.

~~As used herein, a polynucleotide can hybridize to a qualifier if the polynucleotide, or the complement thereof, can hybridize to at least one oligonucleotide probe of the qualifier.~~ In many embodiments, the polynucleotide or the complement thereof can hybridize to at least 50%, 60%, 70%, 80%, 90% or 100% of all of the oligonucleotide probes of the qualifier.

[0089] Each gene or qualifier in Table 3 may have a corresponding SEQ ID NO or Entrez accession number from which the oligonucleotide probes of the qualifier can be derived. In many instances, a polypeptide capable of hybridizing to a qualifier can also hybridize to the sequence of the corresponding SEQ ID NO or Entrez accession number, or the complement thereof. The sequence of each Entrez accession number can be obtained from the Entrez nucleotide database at the National Center of Biotechnology Information (NCBI). The Entrez nucleotide database collects sequences from several sources, including GenBank, RefSeq, and PDB. Each SEQ ID NO may be derived from the sequence of the corresponding Entrez accession number. Table 4 shows the Entrez and Unigene accession numbers for all of the qualifiers on the HgU95A genechip that met the initial criteria.

[0090] Any ambiguous residue ("n") in a SEQ ID NO can be determined by a variety of methods. In one embodiment, the ambiguous residues in a SEQ ID NO are determined by aligning the SEQ ID NO to a corresponding genomic sequence obtained from a human genome sequence database. In another embodiment, the ambiguous residues in a SEQ ID NO are determined based on the sequence of the corresponding Entrez accession number. In yet another embodiment, the ambiguous residues are determined by re-sequencing the SEQ ID NO.

[0091] Genes associated with each qualifier on the HgU95A genechip can be identified based on the annotations provided by Affymetrix. All of the genes thus identified are listed in Tables 3 and 5. These genes can also be identified based on their corresponding Entrez or Unigene accession numbers. In addition, these genes can be determined by BLAST searching their corresponding SEQ ID NOs, or the unambiguous segments thereof, against a human genome sequence database. Suitable human genome sequence databases for this purpose include, but are not limited to, the NCBI human genome database. The NCBI provides BLAST programs, such as "blastn," for searching its sequence databases.

[0092] In one embodiment, the BLAST search of the NCBI human genome database is carried out by using an unambiguous segment (e.g., the longest unambiguous segment) of a SEQ ID NO. Gene(s) that aligns to the unambiguous segment with significant sequence identity can be identified. In many cases, the identified gene(s) has at least 95%, 96%, 97%, 98%, 99%, or more sequence identity with the unambiguous segment.

[0093] On the basis of Spearman's rank correlation, prognosis genes that are highly correlated with TTP or TTD were identified. Table 6a lists examples of genes whose expression levels are positively correlated with TTP. Table 6b depicts examples of genes whose expression levels are negatively correlated with TTP. Table 6c provides examples of genes whose expression levels are positively correlated with TTD. Table 6d shows examples of genes whose expression levels are negatively correlated with TTD. Correlation coefficients, p-values, and the corresponding qualifiers are also indicated for each gene in Tables 6a, 6b, 6c, and 6d.

Table 6a. Prognosis Genes Positively Correlated with TTP

| HgU95A Qualifier | Correlation Coefficient | P-Value | Gene Name |

[0094] In addition to the specific genes described herein, the present invention contemplates the use of any other gene that can hybridize under stringent or nucleic acid array hybridization conditions to a qualifier identified in the present invention. These genes

may include hypothetical or putative genes that are supported by EST or mRNA data. The expression profiles of these genes may correlate with patient clinical outcome. As used herein, a gene can hybridize to a qualifier if an RNA transcript of the gene can hybridize to at least one oligonucleotide probe of the qualifier. In many cases, an RNA transcript of the gene can hybridize to at least 50%, 60%, 70%, 80%, 90%, or more oligonucleotide probes of the qualifier.

[0095] The oligonucleotide probe sequences of each qualifier on HgU95A genechips may be obtained from Affymetrix or from the sequence files maintained at Affymetrix website "www.affymetrix.com/support/technical/byproduct.affx?product=hgu95sequence." For instance, the oligonucleotide probe sequences can be found in the sequence file "HG_U95A Probe Sequences, FASTA" at the website. This sequence file is incorporated herein by reference in its entirety.

[0096] In another example, a Cox proportional hazard regression model was employed to assess the correlation between baseline PBMC gene expression levels and clinical outcome. Cox model can take into account the effects of censoring on correlations of gene expression with TTD (or Survival as of last known date alive) and TTP (or progression-free status as of last known date alive). Of the 45 RCC patients with baseline PBMC expression levels, 4 had censored data for TTP and 15 had censored data for TTD. Similar to the Spearman's assessment of the data, Cox regression can identify genes significantly correlated with survival and disease progression for any given α -confidence level. A similar permutation strategy can be used to affirm any correlation between baseline expression profiles and clinical outcome.

[0097] In one embodiment, models were fit using expression levels from each of the 5,424 qualifiers that passed the initial filtering criteria in the 45 baseline samples. TTP and TTD were tested for their association with log2-transformed scaled frequency at baseline. A SAS program was used to generate the estimates in Tables 7a and 7b. Tables 7a and 7b demonstrate a strong correlation between TTP/TTD and baseline gene expression.

Table 7a. Cox Regressions of Clinical Outcome on Baseline Expression Levels in PBMCs of RCC Patients in CCI-779 Therapy (n = 45 patients)

| Time to Progression | | |
|---------------------|--|--|
| ✓ | Observed Number of Nominally Significant | Percentage of Permutations for which Number of Nominally |

| | Cox Regressions* | Significant Cox Regressions Equals or Exceeds Observed Number** |
|-------|------------------|---|
| 0.1 | 1439 | 0.8% (4/500) |
| 0.05 | 950 | 0.8% (3/500) |
| 0.01 | 342 | 0.8% (4/500) |
| 0.005 | 217 | 0.8% (4/500) |
| 0.001 | 53 | 1.0% (5/500) |

* for 5,424 genes (filtered by at least one Present call and at least one frequency ≥ 10 ppm)

** based on 500 random permutations

Table 7b. Cox Regressions of Clinical Outcome on Baseline Expression Levels in PBMCs of RCC Patients in CCI-779 Therapy (n = 45 patients)

| Time to Death | | |
|---------------|---|--|
| Δ | Observed Number of Nominally Significant Cox Regressions* | Percentage of Permutations for which Number of Nominally Significant Cox Regressions Equals or Exceeds Observed Number** |
| 0.1 | 1948 | <0.2% (0/500) |
| 0.05 | 1383 | <0.2% (0/500) |
| 0.01 | 602 | <0.2% (0/500) |
| 0.005 | 404 | <0.2% (0/500) |
| 0.001 | 142 | <0.2% (0/500) |

* for 5,424 genes (filtered by at least one Present call and at least one frequency ≥ 10 ppm)

** based on 500 random permutations

[0098] Table 8 lists the results of Cox proportional hazard modeling for all of the 5,424 genes that met the initial criteria. Hazard ratios and p-values (for the hypothesis that the risk coefficient was equal to 1, i.e., no risk) are indicated for each gene. Examples of genes that are indicative of high risk for TTP or TTD are shown in Tables 9a or 9c, respectively. These genes have hazard ratios of at least 3. Examples of genes that are indicative of low risk for TTP or TTD are described in Tables 9b or 9d, respectively. These genes have hazard ratios of no more than 0.333.

Table 9a. Prognosis Genes Indicative of High Risk for TTP

WO 2004/097052 A3

(54) Title: METHODS FOR PROGNOSIS AND TREATMENT OF SOLID TUMORS

(57) Abstract: Solid tumor prognosis genes, and methods, systems and equipment of using these genes for the prognosis and treatment of solid tumors. Prognosis genes for a solid tumor can be identified by the present invention. The expression profiles of these genes in peripheral blood mononuclear cells (PBMCs) are correlated with clinical outcome of the solid tumor. The prognosis genes of the present invention can be used as surrogate markers for predicting clinical outcome of a solid tumor in a patient of interest. These genes can also be used to select a treatment which has a favorable prognosis for the solid tumor of the patient of interest.

A. CLASSIFICATION OF SUBJECT MATTER

IPC 7 C12Q1/68 C07K16/18 G01N33/53

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 C12Q G01N

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal, BIOSIS, EMBASE, WPI Data, PAJ, EMBL

C. DOCUMENTS CONSIDERED TO BE RELEVANT

| Category * | Citation of document, with indication, where appropriate, of the relevant passages | Relevant to claim No. |
|------------|--|-----------------------|
| X | <p>BURCZYNSKI ET AL.: "Pharmacogenomic expression profiling of renal cell carcinoma in a phase II trial of CCI-779: identification of surrogate markers of disease and predictors of outcome in the compartment of peripheral blood" EUROPEAN JOURNAL OF CANCER, PERGAMON PRESS, OXFORD, GB, vol. 38, November 2002 (2002-11), page S51, XP002295167 ISSN: 0959-8049 abstract</p> <p style="text-align: center;">-/-</p> | 1-20 |

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents:

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the International filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the International filing date but later than the priority date claimed

- *T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- *X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- *Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- *G* document member of the same patent family

INTERNATIONAL SEARCH REPORT

International application NO.
PCT/US2004/013587

Box II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:

3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this International application, as follows:

see additional sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.

2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:
1-16, 19, 20 (all completely); 17, 18 (partially)

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. claims: Invention 1 (claims 1-16,19,20 (all completely); 17,18 (both partially)):

A method comprising comparing an expression profile of at least one gene in a peripheral blood sample of a patient to at least one reference expression profile of said at least one gene wherein the patient has a solid tumor, and expression levels of each of said at least one gene in PBMCs of patients who have the solid tumor correlate with clinical outcomes of said patients, and wherein in particular the at least one gene is SCML2, the solid tumor is RCC and the clinical outcomes are measured by patient response to a CCI-779 therapy; a system according to claim 19; a nucleic acid or protein according to claim 20.

- Inventions 2-850 (claims 17,18 (both partially)):

A method comprising comparing an expression profile of at least one gene in a peripheral blood sample of a patient to at least one reference expression profile of said at least one gene, wherein the patient has a solid tumor, and expression levels of each of said at least one gene in PBMCs of patients who have the solid tumor correlate with clinical outcomes of said patients, wherein the at least one gene is ITPR3, the solid tumor is RCC and the clinical outcomes are measured by patient response to a CCI-779 therapy.

..ibidem for Inventions 3-850 relating to a different gene selected from tables 6a, 6b, 6c, 6d, 9a, 9b, 9c, 9d, 10, 11, 12, 13, 16, 20 and 21.
